

Musculus rectus abdominis (xlas)

Preview:

simple/clean drawings; lots of additional info (+latin names)

Synonyms: abs; rectus abdominis muscle; straight abdominis muscle; six pack; six-pack; sixpack; rectus

Summary

The *Musculus rectus abdominis*, often referred to as "**abs**" (short for "abdominal muscles"), sits in front of your stomach and is visible on trained and **low body fat** people. In fact, there are two individual muscle cords right next to each other (that's why I'll refer to them in plural). Besides being used for **breathing** the muscles also **bend the torso and lift the pelvis forward** - thus the abs are the main antagonist of the back extensor muscles (*M. erector spinae*). There are **tendons that separate the long muscle cords into packs** for better muscle contraction precision.

Basics

general placement of the *M. rectus abdominis*

some "good to know" things; the size relations are more important than you think

You can read more about "8 packs" in the [advanced](#) section below.

The 1st row of packs deviates on almost every human being. In general this means, if you draw perfectly aligned abs, they will look less natural.

Origin

- Pubic bone (*Os pubis*), more specifically on the **superior pubic ramus** (*Ramus superior*; ramus = branch)
- **Pubic symphysis** (*Symphysis pubica*), that's the cartilage between the two pubic bones

Insertion

- Cartilage of the **5th, 6th and 7th rib** (there is cartilage at the front tip of each rib)
- Some muscle fibers connect to the **breastbone (Sternum)**

origin and insertion; some sources do it the other way round, but it doesn't really matter

Functions

- Bending and crunching the torso forward; the familiar "**sit up**" motion represents this function pretty well
- **Lifting/twisting the pelvis forward**
- Breathing control; the abs are used mainly for **exhaling**

How to draw the muscle

this shape helps you drawing the abs; it's a little more emphasized on female bodies

the two main factors are training and body fat percentage; note that women naturally have more

Advanced

Everything beyond the basics

The **tendinous intersections** (*Intersectiones tendineae*) determine how many packs you can have. **Most people (around 60%)** have 3 intersections which equals to **6 possible packs**. In some media you see people with 8 packs to empathize their strength. The visual effect works, but in reality more packs don't make you stronger. Only around **20% even have 4 intersections = 8 possible packs**, which means its based on luck (genetics) if you are even able to develop an 8 pack. Chances for 2, 4 or 10 packs are even lower than 20%.

a side by side view for 6 and 8 packs; 10 packs just means that there is another intersection below that
